Astro 321 Lecture Notes Set 6 Wayne Hu

Transfer Function

• Transfer function transfers the initial Newtonian curvature to its value today (linear response theory)

$$T(k) = \frac{\Phi(k, a = 1)}{\Phi(k, a_{\text{init}})} \frac{\Phi(k_{\text{norm}}, a_{\text{init}})}{\Phi(k_{\text{norm}}, a = 1)}$$

- Conservation of Bardeen curvature: Newtonian curvature is a constant when stress perturbations are negligible: above the horizon during radiation and dark energy domination, on all scales during matter domination
- When stress fluctuations dominate, perturbations are stabilized by the Jeans mechanism
- Hybrid Poisson equation: Newtonian curvature, comoving density perturbation $\Delta \equiv (\delta \rho/\rho)_{\rm com}$ implies Φ decays

$$(k^2 - 3K)\Phi = 4\pi G\rho\Delta \sim \eta^{-2}\Delta$$

Transfer Function

• Freezing of Δ stops at $\eta_{\rm eq}$

$$\Phi \sim (k\eta_{\rm eq})^{-2}\Delta_H \sim (k\eta_{\rm eq})^{-2}\Phi_{\rm init}$$

- Transfer function has a k^{-2} fall-off beyond $k_{\rm eq} \sim \eta_{\rm eq}^{-1}$
- Small correction since growth with a smooth radiation component is logarithmic not frozen
- Transfer function is a direct output of an Einstein-Boltzmann code

Fitting Function

• Alternately accurate fitting formula exist, e.g. pure CDM form:

$$T(k(q)) = \frac{L(q)}{L(q) + C(q)q^2}$$

$$L(q) = \ln(e + 1.84q)$$

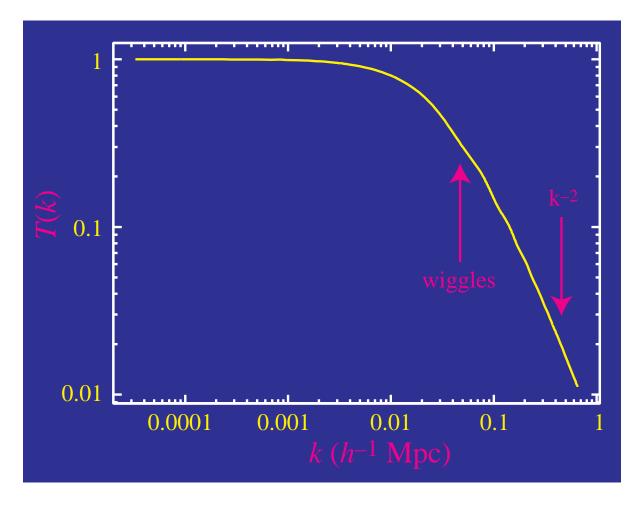

$$C(q) = 14.4 + \frac{325}{1 + 60.5q^{1.11}}$$

$$q = k/\Omega_m h^2 \text{Mpc}^{-1} (T_{\text{CMB}}/2.7K)^2$$

• In h Mpc⁻¹, the critical scale depends on $\Gamma \equiv \Omega_m h$ also known as the shape parameter

Transfer Function

• Numerical calculation

Dark Matter and the Transfer Function

- Baryons caught up in the acoustic oscillations of the CMB and impart acoustic wiggles to the transfer function. Density enhancements are produced kinematically through the continuity equation $\delta_b \sim (k\eta)v_b$ and hence are out of phase with CMB temperature peaks
- Dissipation of the acoustic oscillations eliminates both the CMB and baryon perturbations known as Silk damping for the baryons. This suppression and the general fact that baryons are caught up with photons was one of the main arguments for CDM
- Neutrino dark matter suffers similar effects and hence cannot be the main component of dark matter in the universe

Massive Neutrinos

- Relativistic stresses of a light neutrino slow the growth of structure
- Neutrino species with cosmological abundance contribute to matter as $\Omega_{\nu}h^2 = \sum m_{\nu}/94 {\rm eV}$, suppressing power as $\Delta P/P \approx -8\Omega_{\nu}/\Omega_m$
- Current data from 2dF galaxy survey and CMB indicate $\sum m_{\nu} < 0.9 \mathrm{eV}$ assuming a Λ CDM model with constant tilt based on the shape of the transfer function.

Growth Function

- Same physics applies to the dark energy dominated universe
- Under the dark energy sound horizon or Jeans scale, dark energy density frozen. Potential decays at the same rate for all scales

$$g(a) = \frac{\Phi(k_{\text{norm}}, a)}{\Phi(k_{\text{norm}}, a_{\text{init}})} \qquad ' \equiv \frac{d}{d \ln a}$$

Continuity + Euler + Poisson

$$g'' + \left(1 - \frac{\rho''}{\rho'} + \frac{1}{2} \frac{\rho_c'}{\rho_c}\right) g' + \left(\frac{1}{2} \frac{\rho_c' + \rho'}{\rho_c} - \frac{\rho''}{\rho'}\right) g = 0$$

where ρ is the Jeans unstable matter and ρ_c is the critical density

Dark Energy Growth Suppression

• Pressure growth suppression: $\delta \equiv \delta \rho_m/\rho_m \propto ag$

$$\frac{d^2g}{d\ln a^2} + \left[\frac{5}{2} - \frac{3}{2}w(z)\Omega_{DE}(z)\right] \frac{dg}{d\ln a} + \frac{3}{2}[1 - w(z)]\Omega_{DE}(z)g = 0,$$

where $w \equiv p_{DE}/\rho_{DE}$ and $\Omega_{DE} \equiv \rho_{DE}/(\rho_m + \rho_{DE})$ with initial conditions g = 1, $dg/d \ln a = 0$

- As $\Omega_{DE} \to 0$ g =const. is a solution. The other solution is the decaying mode, elimated by initial conditions
- As $\Omega_{DE} \to 1$ $g \propto a^{-1}$ is a solution. Corresponds to a frozen density field.

- Normalization of potential is set by observations of the CMB, aka
 COBE normalization
- Take the radiation distribution at last scattering to also be described by an isotropic temperature fluctuation field $\Theta(\mathbf{x})$ and recombination to be instantaneous

$$\Theta(\hat{\mathbf{n}}) = \int dD \,\Theta(\mathbf{x}) \delta(D - D_*)$$

where D is the comoving distance and D_* denotes recombination.

Describe the temperature field by its Fourier moments

$$\Theta(\mathbf{x}) = \int \frac{d^3k}{(2\pi)^3} \Theta(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}}$$

Power spectrum

$$\langle \Theta(\mathbf{k})^* \Theta(\mathbf{k}') \rangle = (2\pi)^3 \delta(\mathbf{k} - \mathbf{k}') P_T(k)$$

$$\Delta_T^2 = k^3 P_T / 2\pi^2$$

Temperature field

$$\Theta(\hat{\mathbf{n}}) = \int \frac{d^3k}{(2\pi)^3} \Theta(\mathbf{k}) e^{i\mathbf{k}\cdot D_*\hat{\mathbf{n}}}$$

• Multipole moments $\Theta(\hat{\mathbf{n}}) = \sum_{\ell m} \Theta_{\ell m} Y_{\ell m}$

Expand out plane wave in spherical coordinates

$$e^{i\mathbf{k}D_*\cdot\hat{\mathbf{n}}} = 4\pi \sum_{\ell m} i^{\ell} j_{\ell}(kD_*) Y_{\ell m}^*(\mathbf{k}) Y_{\ell m}(\hat{\mathbf{n}})$$

$$\Theta_{\ell m} = \int \frac{d^3k}{(2\pi)^3} \Theta(\mathbf{k}) 4\pi i^{\ell} j_{\ell}(kD_*) Y_{\ell m}(\mathbf{k})$$

Power spectrum

$$\langle \Theta_{\ell m}^* \Theta_{\ell' m'} \rangle = \int \frac{d^3 k}{(2\pi)^3} (4\pi)^2 (i)^{\ell-\ell'} j_{\ell}(kD_*) j_{\ell'}(kD_*) Y_{\ell m}^*(\mathbf{k}) Y_{\ell' m'}(\mathbf{k}) P_T(k)$$
$$= \delta_{\ell \ell'} \delta_{mm'} 4\pi \int d \ln k \, j_{\ell}^2(kD_*) \Delta_T^2(k)$$

with $\int_0^\infty j_\ell^2(x)d\ln x = 1/(2\ell(\ell+1))$, slowly varying Δ_T^2

• Angular power spectrum:

$$C_{\ell} = \frac{4\pi\Delta_T^2(\ell/D_*)}{2\ell(\ell+1)} = \frac{2\pi}{\ell(\ell+1)}\Delta_T^2(\ell/D_*)$$

- $\ell(\ell+1)C_{\ell}/2\pi = \Delta_T^2$ is commonly used log power
- Sachs-Wolfe effect says $\Delta_T^2 = \Delta_\Phi^2/9$
- Observed number

$$\Delta_T^2 = \left(\frac{28\mu \text{K}}{2.725 \times 10^6 \mu \text{K}}\right)^2$$
$$\Delta_\Phi^2 \approx 9 \times 10^{-10}$$

at recombination

• Today:

$$\Delta_{\Phi}^2 \approx 9 \times 10^{-10} g^2(a) T^2(k) \left(\frac{k}{H_0}\right)^{n-1}$$

Density field

$$k^{2}\Phi = 4\pi G a^{2}\Delta\rho$$

$$= \frac{3}{2}H_{0}^{2}\Omega_{m}\Delta/a$$

$$\Delta_{\Phi}^{2} = \frac{9}{4}\left(\frac{H_{0}}{k}\right)^{4}\Omega_{m}^{2}a^{-2}\Delta_{\Delta}^{2}$$

$$\Delta_{\Delta}^{2} = (2\times10^{-5})^{2}\left(\frac{k}{H_{0}}\right)^{n+3}\Omega_{m}^{-2}a^{2}g^{2}(a)T^{2}(k)$$

Normalization Convention

• Current density field on the horizon scale $k = H_0$

$$\delta_H = 2 \times 10^{-5} \Omega_m^{-1} g(a=1)$$

• In a Λ CDM model, a detailed fit gives

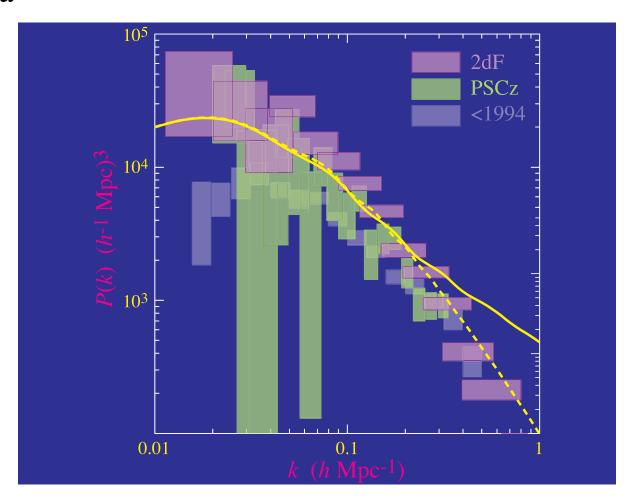

$$\delta_H = 1.94 \times 10^{-5} \Omega_m^{-0.785 - 0.05 \ln \Omega_m} e^{-0.95(n-1) - 0.169(n-1)^2}$$

since growth factor is smaller in a low Ω_m model and normalization scale is not exactly the horizon scale

• In the future (abount now) the COBE normalization will be superceded by CMB peak normalization

Power Spectrum

• 2dF data

• Power spectrum defines large scale structure observables: galaxy clustering, velocity field, Ly α forest clustering, cosmic shear

Velocity field

• Continuity gives the velocity from the density field as

$$v = -\dot{\Delta}/k = -\frac{aH}{k} \frac{d\Delta}{d\ln a}$$
$$= -\frac{aH}{k} \Delta \frac{d\ln(ag)}{d\ln a}$$

- In a Λ CDM model or open model $d \ln(ag)/d \ln a \approx \Omega_m^{0.6}$
- Measuring both the density field and the velocity field (through distance determination and redshift) allows a measurement of Ω_m
- Practically one measures $\beta=\Omega_m^{0.6}/b$ where b is a bias factor for the tracer of the density field, i.e. with galaxy numbers $\delta n/n=b\Delta$
- Can also measure this factor from the redshift space power spectrum - the Kaiser effect where clustering in the radial direction is apparently enhanced by gravitational infall

Lyman- α Forest

- QSO spectra absorbed by neutral hydrogen through the Ly α transition.
- Lack of complete absorption, known as the lack of a Gunn-Peterson trough indicates that the universe is nearly fully ionized out to the highest redshift quasar $z\sim 6$; recently SDSS QSO implies $z\sim 6$ is the end of the reionization epoch
- In ionization equilibrium, the Gunn-Peterson optical depth is a tracer of the underlying baryon density which itself is a tracer of the dark matter $\tau_{GP} \propto \rho_b T^{-0.7}$ with $T(\rho_b)$.
- Clustering in the Ly α forest reflects the underlying linear power spectrum as calibrated through simulations

Gravitational Lensing

• Gravitational potentials along the line of sight $\hat{\mathbf{n}}$ to some source at comoving distance D_s lens the images according to (flat universe)

$$\phi(\hat{\mathbf{n}}) = 2 \int dD \frac{D_s - D}{DD_s} \Phi(D\hat{\mathbf{n}}, \eta(D))$$

remapping image positions as

$$\hat{\mathbf{n}}^I = \hat{\mathbf{n}}^S +
abla_{\hat{\mathbf{n}}} \phi(\hat{\mathbf{n}})$$

• Since absolute source position is unknown, use image distortion defined by the Jacobian matrix

$$\frac{\partial n_i^I}{\partial n_j^S} = \delta_{ij} + \psi_{ij}$$

Weak Lensing

• Small image distortions described by the convergence κ and shear components (γ_1, γ_2)

$$\psi_{ij} = \begin{pmatrix} \kappa - \gamma_1 & -\gamma_2 \\ -\gamma_2 & \kappa + \gamma_1 \end{pmatrix}$$

where $\nabla_{\hat{\mathbf{n}}} = D\nabla$ and

$$\psi_{ij} = 2 \int dD \frac{D(D_s - D)}{D_s} \nabla_i \nabla_j \Phi(D\hat{\mathbf{n}}, \eta(D))$$

• In particular, through the Poisson equation the convergence (measured from shear) is simply the projected mass

$$\kappa = \frac{3}{2}\Omega_m H_0^2 \int dD \frac{D(D_s - D)}{D_s} \frac{\Delta(D\hat{\mathbf{n}}, \eta(D))}{a}$$
