## Covariant Perturbation Theory

- Covariant = takes same form in all coordinate systems
- Invariant = takes the same value in all coordinate systems
- Fundamental equations: Einstein equations, covariant conservation of stress-energy tensor:

$$G_{\mu\nu} = 8\pi G T_{\mu\nu}$$
$$\nabla_{\mu} T^{\mu\nu} = 0$$

• Preserve general covariance by keeping all free variables: 10 for each symmetric 4×4 tensor

1	2	3	4
	5	6	7
		8	9
			10

#### Metric Tensor

- Useful to think in a 3+1 language since there are preferred spatial surfaces where the stress tensor is nearly homogeneous
- In general this is an Arnowitt-Deser-Misner (ADM) split
- Specialize to the case of a nearly FRW metric

$$g_{00} = -a^2, \qquad g_{ij} = a^2 \gamma_{ij} .$$

where the "0" component is conformal time  $\eta = dt/a$  and  $\gamma_{ij}$  is a spatial metric of constant curvature  $K = H_0^2(\Omega_{\text{tot}} - 1)$ .

$$^{(3)}R = \frac{6K}{a^2}$$

#### Metric Tensor

• First define the slicing (lapse function A, shift function  $B^i$ )

$$g^{00} = -a^{-2}(1 - 2A),$$
  

$$g^{0i} = -a^{-2}B^{i},$$

A defines the lapse of proper time between 3-surfaces whereas  $B^i$  defines the threading or relationship between the 3-coordinates of the surfaces

• This absorbs 1+3=4 free variables in the metric, remaining 6 is in the spatial surfaces which we parameterize as

$$g^{ij} = a^{-2}(\gamma^{ij} - 2H_L\gamma^{ij} - 2H_T^{ij}).$$

here (1)  $H_L$  a perturbation to the spatial curvature; (5)  $H_T^{ij}$  a trace-free distortion to spatial metric (which also can perturb the curvature)

#### Curvature Perturbation

• Curvature perturbation on the 3D slice

$$\delta[^{(3)}R] = -\frac{4}{a^2} \left( \nabla^2 + 3K \right) H_L + \frac{2}{a^2} \nabla_i \nabla_j H_T^{ij}$$

- Note that we will often loosely refer to  $H_L$  as the "curvature perturbation"
- We will see that many representations have  $H_T = 0$
- It is easier to work with a dimensionless quantity
- First example of a 3-scalar SVT decomposition

#### Matter Tensor

• Likewise expand the matter stress energy tensor around a homogeneous density  $\rho$  and pressure p:

$$T^{0}_{0} = -\rho - \delta \rho,$$
  
 $T^{0}_{i} = (\rho + p)(v_{i} - B_{i}),$   
 $T^{i}_{0} = -(\rho + p)v^{i},$   
 $T^{i}_{j} = (p + \delta p)\delta^{i}_{j} + p\Pi^{i}_{j},$ 

- (1)  $\delta \rho$  a density perturbation; (3)  $v_i$  a vector velocity, (1)  $\delta p$  a pressure perturbation; (5)  $\Pi_{ij}$  an anisotropic stress perturbation
- So far this is fully general and applies to any type of matter or coordinate choice including non-linearities in the matter, e.g. scalar fields, cosmological defects, exotic dark energy.

## Counting Variables

- Variables (10 metric; 10 matter)
- -10 Einstein equations
  - -4 Conservation equations
  - +4 Bianchi identities
  - -4 Gauge (coordinate choice 1 time, 3 space)
    - 6 Free Variables
- Without loss of generality these can be taken to be the 6 components of the matter stress tensor
- For the background, specify p(a) or equivalently  $w(a) \equiv p(a)/\rho(a)$  the equation of state parameter.

#### Homogeneous Einstein Equations

• Einstein (Friedmann) equations:

$$\left(\frac{1}{a}\frac{da}{dt}\right)^2 = -\frac{K}{a^2} + \frac{8\pi G}{3}\rho \quad \left[=\left(\frac{1}{a}\frac{\dot{a}}{a}\right)^2\right]$$

$$\frac{1}{a}\frac{d^2a}{dt^2} = -\frac{4\pi G}{3}(\rho + 3p) \quad \left[=\frac{1}{a^2}\frac{d}{d\eta}\frac{\dot{a}}{a}\right]$$

so that  $w \equiv p/\rho < -1/3$  for acceleration

• Conservation equation  $\nabla^{\mu}T_{\mu\nu} = 0$  implies

$$\frac{\dot{\rho}}{\rho} = -3(1+w)\frac{\dot{a}}{a}$$

overdots are conformal time but equally true with coordinate time

#### Homogeneous Einstein Equations

• Counting exercise:

- Variables (10 metric; 10 matter)
- -17 Homogeneity and Isotropy
  - -2 Einstein equations
  - -1 Conservation equations
  - +1 Bianchi identities
    - 1 Free Variables

without loss of generality choose ratio of homogeneous & isotropic component of the stress tensor to the density  $w(a) = p(a)/\rho(a)$ .

## Acceleration Implies Negative Pressure

- Role of stresses in the background cosmology
- Homogeneous Einstein equations  $G_{\mu\nu} = 8\pi G T_{\mu\nu}$  imply the two Friedmann equations (flat universe, or associating curvature  $\rho_K = -3K/8\pi G a^2$ )

$$\left(\frac{1}{a}\frac{da}{dt}\right)^2 = \frac{8\pi G}{3}\rho$$

$$\frac{1}{a}\frac{d^2a}{dt^2} = -\frac{4\pi G}{3}(\rho + 3p)$$

so that the total equation of state  $w \equiv p/\rho < -1/3$  for acceleration

• Conservation equation  $\nabla^{\mu}T_{\mu\nu} = 0$  implies

$$\frac{\dot{\rho}}{\rho} = -3(1+w)\frac{\dot{a}}{a}$$

so that  $\rho$  must scale more slowly than  $a^{-2}$ 

#### Scalar, Vector, Tensor

- In linear perturbation theory, perturbations may be separated by their transformation properties under 3D rotation and translation.
- The eigenfunctions of the Laplacian operator form a complete set

$$\nabla^{2}Q^{(0)} = -k^{2}Q^{(0)} \qquad S, 
\nabla^{2}Q_{i}^{(\pm 1)} = -k^{2}Q_{i}^{(\pm 1)} \qquad V, 
\nabla^{2}Q_{ij}^{(\pm 2)} = -k^{2}Q_{ij}^{(\pm 2)} \qquad T,$$

 Vector and tensor modes satisfy divergence-free and transverse-traceless conditions

$$\nabla^{i} Q_{i}^{(\pm 1)} = 0$$

$$\nabla^{i} Q_{ij}^{(\pm 2)} = 0$$

$$\gamma^{ij} Q_{ij}^{(\pm 2)} = 0$$

#### Vector and Tensor Quantities

- A scalar mode carries with it associated vector (curl-free) and tensor (longitudinal) quantities
- A vector mode carries and associated tensor (trace and divergence free) quantities
- A tensor mode has only a tensor (trace and divergence free)
- These are built from the mode basis out of covariant derivatives and the metric

$$Q_{i}^{(0)} = -k^{-1}\nabla_{i}Q^{(0)},$$

$$Q_{ij}^{(0)} = (k^{-2}\nabla_{i}\nabla_{j} + \frac{1}{3}\gamma_{ij})Q^{(0)},$$

$$Q_{ij}^{(\pm 1)} = -\frac{1}{2k}[\nabla_{i}Q_{j}^{(\pm 1)} + \nabla_{j}Q_{i}^{(\pm 1)}],$$

#### Perturbation k-Modes

• For the kth eigenmode, the scalar components become

$$A(\mathbf{x}) = A(k) Q^{(0)}, \qquad H_L(\mathbf{x}) = H_L(k) Q^{(0)},$$
  
$$\delta \rho(\mathbf{x}) = \delta \rho(k) Q^{(0)}, \qquad \delta p(\mathbf{x}) = \delta p(k) Q^{(0)},$$

the vectors components become

$$B_i(\mathbf{x}) = \sum_{m=-1}^{1} B^{(m)}(k) Q_i^{(m)}, \quad v_i(\mathbf{x}) = \sum_{m=-1}^{1} v^{(m)}(k) Q_i^{(m)},$$

and the tensors components

$$H_{Tij}(\mathbf{x}) = \sum_{m=-2}^{2} H_{T}^{(m)}(k) Q_{ij}^{(m)}, \quad \Pi_{ij}(\mathbf{x}) = \sum_{m=-2}^{2} \Pi^{(m)}(k) Q_{ij}^{(m)},$$

Note that the curvature perturbation only involves scalars

$$\delta[^{(3)}R] = \frac{4}{a^2}(k^2 - 3K)(H_L^{(0)} + \frac{1}{3}H_T^{(0)})Q^{(0)}$$

#### Spatially Flat Case

• For a spatially flat background metric, harmonics are related to plane waves:

$$Q^{(0)} = \exp(i\mathbf{k} \cdot \mathbf{x})$$

$$Q_i^{(\pm 1)} = \frac{-i}{\sqrt{2}}(\hat{\mathbf{e}}_1 \pm i\hat{\mathbf{e}}_2)_i \exp(i\mathbf{k} \cdot \mathbf{x})$$

$$Q_{ij}^{(\pm 2)} = -\sqrt{\frac{3}{8}}(\hat{\mathbf{e}}_1 \pm i\hat{\mathbf{e}}_2)_i (\hat{\mathbf{e}}_1 \pm i\hat{\mathbf{e}}_2)_j \exp(i\mathbf{k} \cdot \mathbf{x})$$

where  $\hat{\mathbf{e}}_3 \parallel \mathbf{k}$ . Chosen as spin states, c.f. polarization.

• For vectors, the harmonic points in a direction orthogonal to k suitable for the vortical component of a vector

## Spatially Flat Case

- Tensor harmonics are the transverse traceless gauge representation
- Tensor amplitude related to the more traditional

$$h_{+}[(\mathbf{e}_{1})_{i}(\mathbf{e}_{1})_{j} - (\mathbf{e}_{2})_{i}(\mathbf{e}_{2})_{j}], \qquad h_{\times}[(\mathbf{e}_{1})_{i}(\mathbf{e}_{2})_{j} + (\mathbf{e}_{2})_{i}(\mathbf{e}_{1})_{j}]$$
as

$$h_{+} \pm ih_{\times} = -\sqrt{6}H_{T}^{(\mp 2)}$$

•  $H_T^{(\pm 2)}$  proportional to the right and left circularly polarized amplitudes of gravitational waves with a normalization that is convenient to match the scalar and vector definitions

## Covariant Scalar Equations

DOF counting exercise

- 8 Variables (4 metric; 4 matter)
- -4 Einstein equations
- -2 Conservation equations
- +2 Bianchi identities
- -2 Gauge (coordinate choice 1 time, 1 space)
  - 2 Free Variables

without loss of generality choose scalar components of the stress tensor  $\delta p, \Pi$  .

## Covariant Scalar Equations

• Einstein equations (suppressing 0) superscripts

$$\begin{split} (k^2-3K)[H_L+\frac{1}{3}H_T] - 3(\frac{\dot{a}}{a})^2A + 3\frac{\dot{a}}{a}\dot{H}_L + \frac{\dot{a}}{a}kB = \\ &= 4\pi Ga^2\delta\rho\,, \quad \text{00 Poisson Equation} \\ k^2(A+H_L+\frac{1}{3}H_T) + \left(\frac{d}{d\eta}+2\frac{\dot{a}}{a}\right)(kB-\dot{H}_T) \\ &= -8\pi Ga^2p\Pi\,, \quad ij \text{ Anisotropy Equation} \\ \frac{\dot{a}}{a}A - \dot{H}_L - \frac{1}{3}\dot{H}_T - \frac{K}{k^2}(kB-\dot{H}_T) \\ &= 4\pi Ga^2(\rho+p)(v-B)/k\,, \quad 0i \text{ Momentum Equation} \\ \left[2\frac{\ddot{a}}{a}-2\left(\frac{\dot{a}}{a}\right)^2 + \frac{\dot{a}}{a}\frac{d}{d\eta} - \frac{k^2}{3}\right]A - \left[\frac{d}{d\eta} + \frac{\dot{a}}{a}\right](\dot{H}_L + \frac{1}{3}kB) \\ &= 4\pi Ga^2(\delta p + \frac{1}{3}\delta\rho)\,, \quad ii \text{ Acceleration Equation} \end{split}$$

## Covariant Scalar Equations

Conservation equations: continuity and Navier Stokes

$$\label{eq:continuous_equation} \begin{split} \left[\frac{d}{d\eta} + 3\frac{\dot{a}}{a}\right]\delta\rho + 3\frac{\dot{a}}{a}\delta p &= -(\rho+p)(kv+3\dot{H}_L)\,, \\ \left[\frac{d}{d\eta} + 4\frac{\dot{a}}{a}\right]\left[(\rho+p)\frac{(v-B)}{k}\right] &= \delta p - \frac{2}{3}(1-3\frac{K}{k^2})p\Pi + (\rho+p)A\,, \end{split}$$

- Equations are not independent since  $\nabla_{\mu}G^{\mu\nu}=0$  via the Bianchi identities.
- Related to the ability to choose a coordinate system or "gauge" to represent the perturbations.

#### Covariant Vector Equations

Einstein equations

$$(1 - 2K/k^{2})(kB^{(\pm 1)} - \dot{H}_{T}^{(\pm 1)})$$

$$= 16\pi G a^{2} (\rho + p)(v^{(\pm 1)} - B^{(\pm 1)})/k,$$

$$\left[\frac{d}{d\eta} + 2\frac{\dot{a}}{a}\right] (kB^{(\pm 1)} - \dot{H}_{T}^{(\pm 1)})$$

$$= -8\pi G a^{2} p\Pi^{(\pm 1)}.$$

Conservation Equations

$$\left[\frac{d}{d\eta} + 4\frac{\dot{a}}{a}\right] \left[ (\rho + p)(v^{(\pm 1)} - B^{(\pm 1)})/k \right]$$
$$= -\frac{1}{2}(1 - 2K/k^2)p\Pi^{(\pm 1)},$$

Gravity provides no source to vorticity → decay

## Covariant Vector Equations

DOF counting exercise

- 8 Variables (4 metric; 4 matter)
- -4 Einstein equations
- -2 Conservation equations
- +2 Bianchi identities
- -2 Gauge (coordinate choice 1 time, 1 space)
  - 2 Free Variables

without loss of generality choose vector components of the stress tensor  $\Pi^{(\pm 1)}$ .

## Covariant Tensor Equation

• Einstein equation

$$\left[\frac{d^2}{d\eta^2} + 2\frac{\dot{a}}{a}\frac{d}{d\eta} + (k^2 + 2K)\right]H_T^{(\pm 2)} = 8\pi G a^2 p \Pi^{(\pm 2)}.$$

DOF counting exercise

- 4 Variables (2 metric; 2 matter)
- -2 Einstein equations
- -0 Conservation equations
- +0 Bianchi identities
- -0 Gauge (coordinate choice 1 time, 1 space)

2 Free Variables

wlog choose tensor components of the stress tensor  $\Pi^{(\pm 2)}$ .

## **Arbitrary Dark Components**

- Total stress energy tensor can be broken up into individual pieces
- Dark components interact only through gravity and so satisfy separate conservation equations
- Einstein equation source remains the sum of components.
- To specify an arbitrary dark component, give the behavior of the stress tensor: 6 components:  $\delta p$ ,  $\Pi^{(i)}$ , where i = -2, ..., 2.
- Many types of dark components (dark matter, scalar fields, massive neutrinos,..) have simple forms for their stress tensor in terms of the energy density, i.e. described by equations of state.
- An equation of state for the background  $w = p/\rho$  is *not* sufficient to determine the behavior of the perturbations.

- Geometry of the gauge or time slicing and spatial threading
- For perturbations larger than the horizon, a local observer should just see a different (separate) FRW universe
- Scalar equations should be equivalent to an appropriately remapped Friedmann equation
- Unit normal vector  $N^{\mu}$  to constant time hypersurfaces  $N_{\mu}dx^{\mu}=N_{0}d\eta,\,N^{\mu}N_{\mu}=-1$ , to linear order in metric

$$N_0 = -a(1 + AQ),$$
  $N_i = 0$   
 $N^0 = a^{-1}(1 - AQ),$   $N^i = -BQ^i$ 

Expansion of spatial volume per proper time is given by
 4-divergence

$$\nabla_{\mu} N^{\mu} \equiv \theta = 3H(1 - AQ) + \frac{k}{a}BQ + \frac{3}{a}\dot{H}_{L}Q$$

#### Shear and Acceleration

• Other pieces of  $\nabla_{\nu}N_{\mu}$  give the vorticity, shear and acceleration

$$\nabla_{\nu} N_{\mu} \equiv \omega_{\mu\nu} + \sigma_{\mu\nu} + \frac{1}{3} \theta P_{\mu\nu} - a_{\mu} N_{\nu}$$

with

$$P_{\mu\nu} = g_{\mu\nu} + N_{\mu}N_{\nu}$$

$$\omega_{\mu\nu} = P_{\mu}{}^{\alpha}P_{\nu}{}^{\beta}(\nabla_{\beta}N_{\alpha} - \nabla_{\alpha}N_{\beta})$$

$$\sigma_{\mu\nu} = \frac{1}{2}P_{\mu}{}^{\alpha}P_{\nu}{}^{\beta}(\nabla_{\beta}N_{\alpha} + \nabla_{\alpha}N_{\beta}) - \frac{1}{3}\theta P_{\mu\nu}$$

$$a_{\mu} = (\nabla_{\alpha}N_{\mu})N^{\alpha}$$

projection  $P_{\mu\nu}N^{\nu}=0$ , trace free antisymmetric vorticity, symmetric shear and acceleration

#### Shear and Acceleration

- Vorticity  $\omega_{\mu\nu} = 0$ ,  $\sigma_{00} = \sigma_{0i} = 0 = a_0$
- Remaining perturbed quantities are the spatial shear and acceleration

$$\sigma_{ij} = a(\dot{H}_T - kB)Q_{ij}$$
$$a_i = -kAQ_i$$

- A convenient choice of coordinates might be shear free  $\dot{H}_T kB = 0$
- A alone is related to the perturbed acceleration

• So the e-foldings of the expansion are given by  $d\tau = (1 + AQ)ad\eta$ 

$$N = \int d\tau \frac{1}{3}\theta$$
$$= \int d\eta \left(\frac{\dot{a}}{a} + \dot{H}_L Q + \frac{1}{3}kBQ\right)$$

Thus if kB can be ignored as  $k \to 0$  then  $H_L$  plays the role of a local change in the scale factor, more generally B plays the role of Eulerian  $\to$  Lagrangian coordinates.

- Change in  $H_L$  between separate universes related to change in number of e-folds: so called  $\delta N$  approach, simplifying equations by using N as time variable to absorb local scale factor effects
- We shall see that for adiabatic perturbations  $p(\rho)$  that  $H_L=0$  outside horizon for an appropriate choice of slicing plays an important role in simplifying calculations

• Choosing coordinates where  $\dot{H}_L + kB/3 = 0$  (defines the slicing), the e-folding remains unperturbed, we get that the 00 Einstein equations at  $k \to 0$  are

$$-\left(\frac{\dot{a}}{a}\right)^2 A + \frac{1}{3} \frac{k^2 - 3K}{a^2} (H_L + H_T/3) = \frac{4\pi G}{3} a^2 \delta \rho$$

which is to be compared to the Friedmann equation

$$H^2 + \frac{K}{a^2} = \frac{8\pi G}{3}\rho$$

Noting that  $H = \bar{H}(1 - AQ)$  and using the perturbation to  $^{(3)}\mathcal{R}$ 

$$2\delta H \bar{H} + \frac{\delta K}{a^2} = \frac{8\pi G}{3} \delta \rho Q$$

$$-2AQ\bar{H}^2 + \frac{2}{3} \frac{k^2 - 3K}{a^2} (H_L + H_T/3)Q = \frac{8\pi G}{3} \delta \rho Q$$

$$-\left(\frac{\dot{a}}{a}\right)^2 A + \frac{1}{3} \frac{k^2 - 3K}{a^2} (H_L + H_T/3) = \frac{4\pi G}{3} \delta \rho$$

And the space-space piece

$$\left[2\frac{\ddot{a}}{a} - 2\left(\frac{\dot{a}}{a}\right)^2 + \frac{\dot{a}}{a}\frac{d}{d\eta}\right]A = \frac{4\pi G}{3}a^2(\delta\rho + 3\delta p)$$

which is to be compared with the acceleration equation

$$\frac{d}{d\eta}(aH) = -\frac{4\pi G}{3}a^2(\rho + 3p)$$

again expanding  $H=\bar{H}(1-AQ)$  and also  $d\eta=(1+AQ)d\bar{\eta}$ 

$$\frac{d}{d\eta}(aH) = (1 - AQ)\frac{d}{d\bar{\eta}}(a\bar{H})[1 - AQ]$$

$$\approx \frac{d}{d\bar{\eta}}(a\bar{H}) - 2AQ\frac{d}{d\bar{\eta}}\frac{\dot{a}}{a} + \frac{\dot{a}}{a}\frac{d}{d\bar{\eta}}AQ$$

• Finally the continuity equation (using slicing with  $\dot{H}_L = -kB/3$ )

$$\dot{\delta\rho} + 3\frac{\dot{a}}{a}(\delta\rho + \delta p) = -(\rho + p)k(v - B)$$

is to be compared to

$$d\rho/d\eta = -3(aH)(\rho + p)$$

which again with the substitutions becomes

$$(1 - AQ)\frac{d}{d\bar{\eta}}(\bar{\rho} + \delta\rho Q) = -3(aH)(1 - AQ)[\bar{\rho} + \bar{p}] - 3(aH)[\delta\rho + \delta p]Q$$
$$\frac{d}{d\bar{\eta}}\delta\rho = -3\frac{\dot{a}}{a}(\delta\rho + \delta p)$$

- $\delta \rho / \rho$  constant in  $H_L + kB/3 = 0$  slicing outside horizon where peculiar velocity cannot move matter (cf. Newtonian gauge below).
- Note also that v-B has a special interpretation as well: setting v=B gives a comoving slicing since  $N^i \propto v^i$ ,  $N_i \propto v_i B_i = 0$

- There are other possible choices what to hold fixed on constant time slices besides  $N = \ln a$ . While separate universe statements still hold a must be perturbed and the simplest gauge to see these identifications with the Friedmann equations changes.
- More generally the analysis of the normal to constant time surfaces has identified geometric quantities associated with the metric perturbations
- Uniform efolding:  $\dot{H}_L + kB/3 = 0$
- Shear free:  $\dot{H}_T kB = 0$
- Zero acceleration, coordinate and proper time coincide: A=0
- Uniform expansion:  $-3HA + (3\dot{H}_L + kB) = 0$
- Comoving: v = B

#### Gauge

- Metric and matter fluctuations take on different values in different coordinate system
- No such thing as a "gauge invariant" density perturbation!
- General coordinate transformation:

$$\tilde{\eta} = \eta + T$$
 $\tilde{x}^i = x^i + L^i$ 

free to choose  $(T, L^i)$  to simplify equations or physics - corresponds to a choice of slicing and threading in ADM.

• Decompose these into scalar T,  $L^{(0)}$  and vector harmonics  $L^{(\pm 1)}$ .

#### Gauge

•  $g_{\mu\nu}$  and  $T_{\mu\nu}$  transform as tensors, so components in different frames can be related

$$\tilde{g}_{\mu\nu}(\tilde{\eta}, \tilde{x}^{i}) = \frac{\partial x^{\alpha}}{\partial \tilde{x}^{\mu}} \frac{\partial x^{\beta}}{\partial \tilde{x}^{\nu}} g_{\alpha\beta}(\eta, x^{i}) 
= \frac{\partial x^{\alpha}}{\partial \tilde{x}^{\mu}} \frac{\partial x^{\beta}}{\partial \tilde{x}^{\nu}} g_{\alpha\beta}(\tilde{\eta} - TQ, \tilde{x}^{i} - LQ^{i})$$

- Fluctuations are compared at the same coordinate positions (not same space time positions) between the two gauges
- For example with a TQ perturbation, an event labeled with  $\tilde{\eta}=$ const. and  $\tilde{x}=$ const. represents a different time with respect to the underlying homogeneous and isotropic background

#### Gauge Transformation

• Scalar Metric:

$$\tilde{A} = A - \dot{T} - \frac{\dot{a}}{a}T,$$
 $\tilde{B} = B + \dot{L} + kT,$ 
 $\tilde{H}_{L} = H_{L} - \frac{\dot{k}}{3}L - \frac{\dot{a}}{a}T,$ 
 $\tilde{H}_{T} = H_{T} + kL, \qquad \tilde{H}_{L} + \frac{1}{3}\tilde{H}_{T} = H_{L} + \frac{1}{3}H_{T} - \frac{\dot{a}}{a}T$ 

curvature perturbation depends on slicing not threading

Scalar Matter (Jth component):

$$\delta \tilde{\rho}_J = \delta \rho_J - \dot{\rho}_J T,$$
 $\delta \tilde{p}_J = \delta p_J - \dot{p}_J T,$ 
 $\tilde{v}_J = v_J + \dot{L},$ 

density and pressure likewise depend on slicing only

#### Gauge Transformation

• Vector:

$$\tilde{B}^{(\pm 1)} = B^{(\pm 1)} + \dot{L}^{(\pm 1)}, 
\tilde{H}_{T}^{(\pm 1)} = H_{T}^{(\pm 1)} + kL^{(\pm 1)}, 
\tilde{v}_{J}^{(\pm 1)} = v_{J}^{(\pm 1)} + \dot{L}^{(\pm 1)},$$

• Spatial vector has no background component hence no dependence on slicing at first order

Tensor: no dependence on slicing or threading at first order

- Gauge transformations and covariant representation can be extended to higher orders
- A coordinate system is fully specified if there is an explicit prescription for  $(T, L^i)$  or for scalars (T, L)

## Slicing

Common choices for slicing T: set something geometric to zero

- Proper time slicing A=0: proper time between slices corresponds to coordinate time T allows c/a freedom
- Comoving (velocity orthogonal) slicing: v-B=0, matter 4 velocity is related to  $N^{\nu}$  and orthogonal to slicing T fixed
- Newtonian (shear free) slicing:  $\dot{H}_T kB = 0$ , expansion rate is isotropic, shear free, T fixed
- Uniform expansion slicing:  $-(\dot{a}/a)A + \dot{H}_L + kB/3 = 0$ , perturbation to the volume expansion rate  $\theta$  vanishes, T fixed
- Flat (constant curvature) slicing,  $\delta^{(3)}R = 0$ ,  $(H_L + H_T/3 = 0)$ , T fixed
- Constant density slicing,  $\delta \rho_I = 0$ , T fixed

## Threading

ullet Threading specifies the relationship between constant spatial coordinates between slices and is determined by L

Typically involves a condition on v, B,  $H_T$ 

- Orthogonal threading B=0, constant spatial coordinates orthogonal to slicing (zero shift), allows  $\delta L=c$  translational freedom
- Comoving threading v = 0, allows  $\delta L = c$  translational freedom.
- Isotropic threading  $H_T = 0$ , fully fixes L

# Newtonian (Longitudinal) Gauge

• Newtonian (shear free slicing, isotropic threading):

$$ilde{B} = ilde{H}_T = 0$$
 $\Psi \equiv ilde{A}$  (Newtonian potential)
 $\Phi \equiv ilde{H}_L$  (Newtonian curvature)
 $L = -H_T/k$ 
 $T = -B/k + \dot{H}_T/k^2$ 

Good: intuitive Newtonian like gravity; matter and metric algebraically related; commonly chosen for analytic CMB and lensing work

Bad: numerically unstable

# Newtonian (Longitudinal) Gauge

• Newtonian (shear free) slicing, isotropic threading  $B = H_T = 0$ :

$$(k^2-3K)\Phi = 4\pi Ga^2 \left[\delta\rho + 3\frac{\dot{a}}{a}(\rho+p)v/k\right]$$
 Poisson + Momentum  $k^2(\Psi+\Phi) = -8\pi Ga^2p\Pi$  Anisotropy

so  $\Psi = -\Phi$  if anisotropic stress  $\Pi = 0$  and

$$\begin{bmatrix} \frac{d}{d\eta} + 3\frac{\dot{a}}{a} \end{bmatrix} \delta\rho + 3\frac{\dot{a}}{a}\delta p = -(\rho + p)(kv + 3\dot{\Phi}), 
\begin{bmatrix} \frac{d}{d\eta} + 4\frac{\dot{a}}{a} \end{bmatrix} (\rho + p)v = k\delta p - \frac{2}{3}(1 - 3\frac{K}{k^2})p k\Pi + (\rho + p) k\Psi,$$

- Newtonian competition between stress (pressure and viscosity)
   and potential gradients
- Note: Poisson source is the density perturbation on comoving slicing

#### Total Matter Gauge

• Total matter: (comoving slicing, isotropic threading)

$$ilde{B} = ilde{v} \quad (T_i^0 = 0)$$
 $ilde{H}_T = 0$ 
 $ilde{\xi} = ilde{A}$ 
 $ilde{\mathcal{R}} = ilde{H}_L \quad \text{(comoving curvature)}$ 
 $ilde{\Delta} = ilde{\delta} \quad \text{(total density pert)}$ 
 $ilde{T} = (v - B)/k$ 
 $ilde{L} = -H_T/k$ 

Good: Algebraic relations between matter and metric; comoving curvature perturbation obeys conservation law

Bad: Non-intuitive threading involving v

#### Total Matter Gauge

 Euler equation becomes an algebraic relation between stress and potential

$$(\rho + p)\xi = -\delta p + \frac{2}{3}\left(1 - \frac{3K}{k^2}\right)p\Pi$$

• Einstein equation lacks momentum density source

$$\frac{\dot{a}}{a}\xi - \dot{\mathcal{R}} - \frac{K}{k^2}kv = 0$$

Combine:  $\mathcal{R}$  is conserved if stress fluctuations negligible, e.g. above the horizon if  $|K| \ll H^2$ 

$$\dot{\mathcal{R}} + Kv/k = \frac{\dot{a}}{a} \left[ -\frac{\delta p}{\rho + p} + \frac{2}{3} \left( 1 - \frac{3K}{k^2} \right) \frac{p}{\rho + p} \Pi \right] \to 0$$

# "Gauge Invariant" Approach

- Gauge transformation rules allow variables which take on a geometric meaning in one choice of slicing and threading to be accessed from variables on another choice
- Functional form of the relationship between the variables is gauge invariant (not the variable values themselves! – i.e. equation is covariant)
- E.g. comoving curvature and density perturbations

$$\mathcal{R} = H_L + \frac{1}{3}H_T - \frac{\dot{a}}{a}(v - B)/k$$

$$\Delta \rho = \delta \rho + 3(\rho + p)\frac{\dot{a}}{a}(v - B)/k$$

## Newtonian-Total Matter Hybrid

- With the gauge in(or co) variant approach, express variables of one gauge in terms of those in another allows a mixture in the equations of motion
- Example: Newtonian curvature and comoving density

$$(k^2 - 3K)\Phi = 4\pi Ga^2\rho\Delta$$

ordinary Poisson equation then implies  $\Phi$  approximately constant if stresses negligible.

 Example: Exact Newtonian curvature above the horizon derived through comoving curvature conservation
 Gauge transformation

$$\Phi = \mathcal{R} + \frac{\dot{a}}{a} \frac{v}{k}$$

# Hybrid "Gauge Invariant" Approach

Einstein equation to eliminate velocity

$$\frac{\dot{a}}{a}\Psi - \dot{\Phi} = 4\pi Ga^2(\rho + p)v/k$$

Friedmann equation with no spatial curvature

$$\left(\frac{\dot{a}}{a}\right)^2 = \frac{8\pi G}{3}a^2\rho$$

With  $\dot{\Phi} = 0$  and  $\Psi \approx -\Phi$ 

$$\frac{\dot{a}}{a}\frac{v}{k} = -\frac{2}{3(1+w)}\Phi$$

# Newtonian-Total Matter Hybrid

Combining gauge transformation with velocity relation

$$\Phi = \frac{3+3w}{5+3w}\mathcal{R}$$

Usage: calculate  $\mathcal{R}$  from inflation determines  $\Phi$  for any choice of matter content or causal evolution.

• Example: Scalar field ("quintessence" dark energy) equations in total matter gauge imply a sound speed  $\delta p/\delta \rho=1$  independent of potential  $V(\phi)$ . Solve in synchronous gauge.

## Synchronous Gauge

• Synchronous: (proper time slicing, orthogonal threading)

$$\tilde{A} = \tilde{B} = 0$$

$$\eta_T \equiv -\tilde{H}_L - \frac{1}{3}\tilde{H}_T$$

$$h_L \equiv 6H_L$$

$$T = a^{-1} \int d\eta aA + c_1 a^{-1}$$

$$L = -\int d\eta (B + kT) + c_2$$

Good: stable, the choice of numerical codes

Bad: residual gauge freedom in constants  $c_1$ ,  $c_2$  must be specified as an initial condition, intrinsically relativistic, threading conditions breaks down beyond linear regime if  $c_1$  is fixed to CDM comoving.

# Synchronous Gauge

The Einstein equations give

$$\dot{\eta}_T - \frac{K}{2k^2} (\dot{h}_L + 6\dot{\eta}_T) = 4\pi G a^2 (\rho + p) \frac{v}{k} ,$$

$$\ddot{h}_L + \frac{\dot{a}}{a} \dot{h}_L = -8\pi G a^2 (\delta \rho + 3\delta p) ,$$

$$-(k^2 - 3K) \eta_T + \frac{1}{2} \frac{\dot{a}}{a} \dot{h}_L = 4\pi G a^2 \delta \rho$$

[choose (1 & 2) or (1 & 3)] while the conservation equations give

$$\[ \frac{d}{d\eta} + 3\frac{\dot{a}}{a} \] \delta\rho_J + 3\frac{\dot{a}}{a}\delta p_J = -(\rho_J + p_J)(kv_J + \frac{1}{2}\dot{h}_L),$$

$$\[ \frac{d}{d\eta} + 4\frac{\dot{a}}{a} \] (\rho_J + p_J)\frac{v_J}{k} = \delta p_J - \frac{2}{3}(1 - 3\frac{K}{k^2})p_J\Pi_J.$$

# Synchronous Gauge

- Lack of a lapse A implies no gravitational forces in Navier-Stokes equation. Hence for stress free matter like cold dark matter, zero velocity initially implies zero velocity always.
- Choosing the momentum and acceleration Einstein equations is good since for CDM domination, curvature  $\eta_T$  is conserved and  $\dot{h}_L$  is simple to solve for.
- Choosing the momentum and Poisson equations is good when the equation of state of the matter is complicated since  $\delta p$  is not involved. This is the choice of CAMB.

Caution: since the curvature  $\eta_T$  appears and it has zero CDM source, subtle effects like dark energy perturbations are important everywhere

# Spatially Flat Gauge

• Spatially Flat (flat slicing, isotropic threading):

$$ilde{H}_L = ilde{H}_T = 0$$
 $L = -H_T/k$ 
 $ilde{A}, ilde{B} = ext{metric perturbations}$ 
 $T = \left(\frac{\dot{a}}{a}\right)^{-1} \left(H_L + \frac{1}{3}H_T\right)$ 

Good: eliminates spatial metric in evolution equations; useful in inflationary calculations (Mukhanov et al)

Bad: non-intuitive slicing (no curvature!) and threading

• Caution: perturbation evolution is governed by the behavior of stress fluctuations and an isotropic stress fluctuation  $\delta p$  is gauge dependent.

• Uniform density: (constant density slicing, isotropic threading)

$$H_T = 0$$
,  
 $\zeta_I \equiv H_L$   
 $B_I \equiv B$   
 $A_I \equiv A$   
 $T = \frac{\delta \rho_I}{\dot{\rho}_I}$   
 $L = -H_T/k$ 

Good: Curvature conserved involves only stress energy conservation; simplifies isocurvature treatment

Bad: non intuitive slicing (no density pert! problems beyond linear regime) and threading

• Einstein equations with I as the total or dominant species

$$(k^{2} - 3K)\zeta_{I} - 3\left(\frac{\dot{a}}{a}\right)^{2} A_{I} + 3\frac{\dot{a}}{a}\dot{\zeta}_{I} + \frac{\dot{a}}{a}kB_{I} = 0,$$

$$\frac{\dot{a}}{a}A_{I} - \dot{\zeta}_{I} - \frac{K}{k}B_{I} = 4\pi Ga^{2}(\rho + p)\frac{v - B_{I}}{k},$$

• The conservation equations (if J = I then  $\delta \rho_J = 0$ )

$$\[ \left[ \frac{d}{d\eta} + 3\frac{\dot{a}}{a} \right] \delta\rho_J + 3\frac{\dot{a}}{a} \delta p_J = -(\rho_J + p_J)(kv_J + 3\dot{\zeta}_I) , \\ \left[ \frac{d}{d\eta} + 4\frac{\dot{a}}{a} \right] (\rho_J + p_J) \frac{v_J - B_I}{k} = \delta p_J - \frac{2}{3}(1 - 3\frac{K}{k^2})p_J\Pi_J + (\rho_J + p_J)A_I .$$

Conservation of curvature - single component I

$$\dot{\zeta}_I = -\frac{\dot{a}}{a} \frac{\delta p_I}{\rho_I + p_I} - \frac{1}{3} k v_I \,.$$

- Since  $\delta \rho_I = 0$ ,  $\delta p_I$  is the non-adiabatic stress and curvature is constant as  $k \to 0$  for internally adiabatic stresses  $p_I(\rho_I)$ .
- Note that this conservation law does not involve the Einstein equations at all: just local energy momentum conservation so it is valid for alternate theories of gravity
- Curvature on comoving slices  $\mathcal{R}$  and  $\zeta_I$  related by

$$\zeta_I = \mathcal{R} + \frac{1}{3} \frac{\rho_I \Delta_I}{(\rho_I + p_I)} \Big|_{\text{comoving}}.$$

and coincide above the horizon for adiabatic fluctuations

 Simple relationship to density fluctuations in the spatially flat gauge

$$\zeta_I = \frac{1}{3} \frac{\delta \tilde{\rho}_I}{(\rho_I + p_I)} \Big|_{\text{flat}}.$$

- For each particle species  $\delta \rho/(\rho+p)=\delta n/n$ , the number density fluctuation
- Multiple  $\zeta_J$  carry information about number density fluctuations between species
- $\zeta_J$  constant component by component outside horizon if each component is adiabatic  $p_J(\rho_J)$ .

#### Vector Gauges

- Vector gauge depends only on threading L
- Poisson gauge: orthogonal threading  $B^{(\pm 1)}=0$ , leaves constant L translational freedom
- Isotropic gauge: isotropic threading  $H_T^{(\pm 1)} = 0$ , fixes L
- To first order scalar and vector gauge conditions can be chosen separately
- More care required for second and higher order where scalars and vectors mix
